Super Resolution Microscopes

Nikon

Super Resolution Microscopes
A brand new era in super resolution

N-SIM S
Structured illumination microscopy
15 fps image acquisition
Lateral resolution of ~115 nm
Axial resolution of ~269 nm
The N-SIM S Super Resolution Microscope utilizes a unique high-speed structured illumination system to achieve acquisition speeds of up to 15 fps*, enabling fast biological processes to be captured at twice the spatial resolution of conventional light microscopes (~115 nm** in XY).

The N-STORM Super Resolution Microscope achieves a 10-fold improvement in resolution compared to conventional light microscopes (~20 nm in XY), enabling observation at the true molecular level.

The N-SIM S and N-STORM can be easily combined within the same imaging system for greater flexibility in nanoscale imaging experiments. They can be further combined with confocal microscope system such as the A1+ to create a single versatile platform for multi-scale imaging. Powered at the core by the industry-leading Ti2 inverted microscope with its ultra-flexible design, nano-precision Z-drive and Perfect Focus System, the possibilities for experimental design are limitless.

* 2D-SIM mode, 512 x 512 pixels, 2 msec exposure time
** FWHM of 100 nm bead images collected in 3D-SIM mode, using 488 nm excitation laser. In TIRF-SIM mode, 86 nm is achieved using 40 nm beads excited by a 488 nm laser.

The N-SIM S combines innovative structured illumination microscopy technology with unparalleled optics to double the resolution of conventional light microscopes. With acquisition speeds of up to 15 fps, the N-SIM S enables high-speed super resolution imaging of dynamic events in live cells.

- Captures rapid changes in live cells at 15 fps*
- Twice the resolution of conventional light microscopes (approx. 115 nm**), utilizing structured illumination microscopy
- Automatic switching between different illumination modes
- Two-channel TIRF-SIM acquisition
- Acquires larger fields of view (66 µm x 66 µm***)
- Compatible with easy-to-use dry objectives
- Simultaneous two-channel imaging (optional)

* 2D-SIM mode; 512 x 512 pixels, 2 msec exposure time
** FWHM of 100 nm bead images collected in 3D-SIM mode, using 488 nm excitation laser. In TIRF-SIM mode, 86 nm is achieved using 40 nm beads excited by a 488 nm laser.

Capture rapid changes in live cells

High-speed super-resolution imaging at 15 fps

Nikon’s new high-speed structured illumination system utilizes a novel pattern modulation technology to generate fast and precise switching of illumination patterns. The N-SIM S Super Resolution Microscope achieves incredible acquisition speeds (up to 15 fps*), enabling super-resolution time-lapse imaging of live cells and intracellular dynamics. Discover a new level of live-cell imaging with the N-SIM S.

Easily switch between imaging modes for optimal results

Automatic switching between illumination modes

Newly-developed, high-speed structured illumination technology not only enables fast acquisition rates but also automatic switching between illumination modes and automated optimization of structured illumination patterns for different wavelengths and magnifications. This expanded automation enables fast 2-color TIRF-SIM imaging as well as multiplexing of different SIM modalities. The N-SIM S provides easy-to-use, streamlined workflows, whether it be for single-mode or multi-modal imaging experiments.

Acquire larger fields of view

The N-SIM S can acquire super-resolution images with a large field of view of 66 µm square. This larger imaging area enables very high throughput for applications/samples that benefit from larger fields of view, such as neurons, reducing the amount of time and effort required to obtain data.
Simultaneous two-channel imaging

Simultaneous two-color imaging is possible by utilizing an optional Two Camera Imaging Adaptor* and two sCMOS cameras.

* Andor Technology Ltd.

2D-SIM mode/TIRF-SIM mode

This mode captures super-resolution 2D images at high speed with incredible contrast. The TIRF-SIM mode enables Total Internal Reflection Fluorescence observation at double the resolution of conventional TIRF microscopes, facilitating a greater understanding of molecular interactions at the cell surface.

3D-SIM mode

The 3D-SIM mode generates structured illumination patterns in three dimensions to deliver a two-fold improvement in lateral and axial resolution. Two reconstruction methods (“slice” and “stack”) are available to optimize results for application requirements (e.g. sample thickness, speed, etc.).

The principle of Structured Illumination Microscopy

Analytical processing of recorded moiré patterns, produced by overlaying a known high spatial frequency pattern, mathematically restores the sub-resolution structure of a specimen.

Utilization of high spatial frequency laser interference to illuminate sub-resolution structures within a specimen produces moiré fringes, which are captured. These moiré fringes include modulated information of the sub-resolution structure of the specimen. Through image processing, the unknown specimen information can be recovered to achieve resolution beyond the limit of conventional light microscopes.

Create super-resolution images by processing multiple moiré pattern images

An image of moiré patterns captured in this process includes information of the minute structures within a specimen. Multiple phases and orientations of structured illumination are captured, and the displaced "super-resolution" information is extracted from moiré fringe information. This information is combined mathematically in "Fourier" or aperture space and then transformed back into image space, creating an image at double the conventional resolution limit.

Utilizing high-frequency striped illumination to double the resolution

The capture of high resolution, high spatial frequency information is limited by the Numerical Aperture (NA) of the objectives, and spatial frequencies of structure beyond the optical system aperture are excluded (Fig. A). Illuminating the specimen with high frequency structured illumination, which is multiplied by the unknown structure in the specimen beyond the classical resolution limit, brings the displaced "super-resolution" information within the optical system aperture (Fig. B).

When this "super-resolution" information is then mathematically combined with the standard information captured by the objective lens, it results in resolutions equivalent to those captured with objective lenses with approximately double the NA (Fig. C).

Fig. A: Resolution is limited by the NA of the objective.

Fig. B: The product of Structured Illumination and normally un-resolvable specimen structure produce recordable moiré fringes containing the specimen information at double the conventional resolution limit.

Fig. C: Images with resolutions equivalent to those captured with objective lenses with approximately double the NA are achieved.

Experience the nanoscale universe
STochastic Optical Reconstruction Microscopy (STORM) reconstructs a super-resolution image by combining precise localization information for individual fluorophores in complex fluorescent microscope specimens. The N-STORM takes advantage of Nikon’s powerful Ti2-E inverted microscope and applies high-precision multi-color localization and reconstruction in three dimensions (xyz) to enable super-resolution imaging at tenfold the resolution of conventional light microscopes (up to 20 nm in xy). This powerful technology enables visualization of molecular interactions and organizations at the nanoscopic scale, opening up new worlds of scientific understanding.

❖ 10 times the resolution of conventional light microscopes in x, y and z directions
❖ Dynamic super resolution imaging at the molecule level
❖ Multi-color imaging capability
❖ High definition, high density images
❖ Large image acquisition area
Tenfold increased resolution in x, y and z

Up to 50 nm axial resolution

In addition to lateral super-resolution, the N-STORM utilizes proprietary methods to achieve a tenfold enhancement in axial resolution over conventional light microscopes and provide nanoscale information in 3D. The 3D-Stack function allows multiple 3D-STORM images from different Z positions to be captured and stitched into one image to create thicker STORM images.
Up to 20 nm lateral resolution

The N-STORM utilizes high-precision localization information from thousands of individual fluorophores present in a field of view to create breathtaking “super-resolution” images, exhibiting spatial resolution 10 times greater than conventional light microscopes.

N-STORM images

Dynamic super resolution imaging

Newly developed optics and illumination systems, optimized for sCMOS technology, have increased image acquisition speeds by up to 10 times. With acquisition times reduced from minutes to seconds*, dynamic events in live specimens can now be captured with molecular level resolution.

* Using high-speed mode (20 μm x 20 μm imaging area)

Time-lapse STORM images of African green monkey kidney cell (BSC-1) labeled with Mito-Tracker Red (Mitochondria).

Imaging speed: 500 fps
28 sec time-lapse imaging with 2 sec interval
Scale bar: 0.2 μm

Multi-color imaging capability

Multi-color super-resolution imaging can be carried out using both activator-reporter pairs for sequential activation imaging and activator-free labels for continuous activation imaging. This flexibility allows users to easily gain critical insights into the localization and interaction properties of multiple proteins at the molecular level.

3-color STORM image of a CV-1 cell stained with antibodies against alpha-tubulin (Alexa Fluor® 647; magenta), caveolin (Alexa Fluor® 555; red), and with Alexa Fluor® 488-phalloidin (green) for F-actin.
High definition, high density images

Newly developed excitation optics and improved image acquisition rates provide increased molecule localization density, resulting in clearer images of macromolecular structures.

Large image acquisition area

New intermediate zoom lenses in the imaging system have been developed and optimized for a wide field of view. The wide-view mode achieves 80 μm x 80 μm, a 4-fold increase in imaging area compared to previous models.

4 times wider imaging area, 80 μm x 80 μm (wide-view mode). Conventional imaging area of 40 μm x 40 μm also shown for comparison.
Sample: Mitochondria TOM20 conjugated with Alexa Fluor® 647
**STochastic Optical Reconstruction Microscopy (STORM)** reconstructs a super-resolution image by combining high-accuracy localization information of individual fluorophores in three dimensions and multiple colors.

N-STORM uses stochastic activation of relatively small numbers of fluorophores using very low-intensity light. This random stochastic “activation” of fluorophores allows temporal separation of individual molecules, enabling high precision Gaussian fitting of each fluorophore image in XY. By utilizing special 3D-STORM optics, N-STORM can also localize individual molecules along the Z-axis with high precision. Computationally combining molecular coordinates in three dimensions results in super-resolution 3D images of the nanoscopic world.

**High-precision Z-axis position detection**

Using a cylindrical lens that asymmetrically condenses light beams in either X or Y direction, Z-axis molecule locations can be determined with an accuracy of about 50 nm. Location in Z is determined by detecting the orientation of the astigmatism-induced stretch in the X or Y direction and the size of the out-of-focus point images. 3D fluorescent images can be reconstructed by combining the determined Z-axis location information with XY-axis location information.

**Variety of photoswitchable probes and labeling approaches for high localization accuracy**

Various types of activator-reporter pairs and activator-free labels are available. The activator-reporter dye pair approach provides consistent localization accuracy between channels by leveraging the same reporter dye for different channels. Each dye pair consists of an activator dye and reporter dye, with the activator dye regulating the activation state of the reporter dye. Activator-free labels consist of imaging dye only, enabling simple labeling and sample preparation techniques such as conventional indirect immunofluorescence using conventional dye-conjugated antibodies.

---

**Reconstruction of N-STORM images using localization information of individual fluorophores**

**Conventional fluorescent microscopy**

- **Excite all fluorophores**
- **Individual localization information cannot be detected**

**N-STORM processing**

- **Activates with very low-intensity light**
- **Excites with strong light**
- **Detects the center location**

**Plot detected localization information**

Super resolution image

---

**Sequence of activation illumination with activator-reporter pair**

STEP 1 Most activator-reporter dye pairs are converted to a non-emissive state by combining them with high intensity light

STEP 2 Absorption of light by an activator results in transfer of energy to a nearby reporter dye, accelerating the transition of the reporter dye from a non-emissive to a ground state. The use of spectrally distinct activator dyes allows for the use of the same reporter dye for multiple imaging channels.

STEP 3 High intensity illumination results in fluorescence emission from the activated reporter dye.

**Sequence of activation illumination with activator-free label**

STEP 1 Activator-free reporter dye is converted to a non-emissive state by combining it with high intensity light

STEP 2 The reporter dye will stochastically relax to the ground state and then be excited to the fluorescent state by ongoing high intensity illumination.

* Required when used with confocal system
Ultra-stable platforms for super-resolution imaging

Slight changes in temperature and minor vibrations in the imaging environment can greatly impact focus stability, which in turn can be detrimental to super-resolution imaging. The ECLIPSE Ti2-E motorized inverted research microscope has been designed with dramatically improved focus stability and an automatic real-time focus correction system to eliminate focus drift, enabling faithful visualization of nanoscopic cell details.
High-stability Z-focusing mechanism
The durable body of the Ti2-E provides a highly stable platform for super-resolution microscopes. The Ti2-E minimizes vibrations by downsizing the Z-focusing mechanism and positioning it adjacent to the nosepiece, providing the superior Z-focusing precision and stability required for super-resolution imaging.

Auto correction collar
Super-resolution imaging is highly sensitive to spherical aberrations. An automatic correction collar enables easy and precise correction collar adjustment to compensate for spherical aberrations, ensuring consistently high quality super-resolution images.

Real-time focus correction with PFS
The Perfect Focus System (PFS) maintains focus by automatically tracking and maintaining the desired Z position. PFS corrects focus drift, caused by minute temperature changes and vibrations, in real time. The detector portion of the PFS is separated from the nosepiece to minimize mechanical load and heat transfer, further reducing the potential for Z-drifts.
Highest performance optics for super-resolution imaging

Nikon has developed dedicated objectives for super-resolution imaging to realize bright and precise nanoscale images. The SR objectives are aligned and inspected using wavefront aberration measurement technologies to ensure the lowest possible asymmetric aberration and superb optical performance required for super-resolution imaging.
Silicone immersion objectives
Silicone immersion objectives use high viscosity silicone oil with a refractive index close to that of live cells as an immersion liquid. Because of this improved refractive index compatibility, these objectives can provide improved photon collection capability and resolution when performing super-resolution imaging deeper into the specimen. They exhibit superior chromatic aberration correction and high transmittance over a broad range of wavelengths.

Silicon immersion objective  Oil immersion objective

Oil immersion objectives
These objectives provide the high numerical apertures required for N-STORM imaging. The HP objectives are compatible with the ultrahigh power lasers required for inducing rapid photoswitching of fluorophores. They provide improved axial chromatic aberration correction to achieve the highest level of precision in localization and image alignment for 3D multi-color STORM imaging.

Water immersion objectives
These objectives correct chromatic aberration over a wide range of wavelengths up to near-IR, enabling high-resolution deep imaging of live cells. The AC-type objectives that support the Auto Correction Collar of the Ti2-E microscope allow precise and easy adjustment of the correction collar.

Dry objectives
The N-SIM S is compatible with dry objectives, making both super-resolution imaging and confocal imaging available without switching lenses. Low-magnification, wide field-of-view dry lenses enable high resolution observation even at the periphery of sample tissues.

*Dry objectives support 2D-SIM and 3D-SIM (slice reconstruction) only

*With cover glass thickness of 0.17 mm
Unified acquisition and analysis software platform

NIS-Elements, Nikon’s unified software platform, provides an intuitive workflow for super-resolution imaging. Combined with graphical programming tools such as JOBS and illumination sequence, as well as powerful analysis and visualization tools, NIS-Elements creates a comprehensive operating environment that can be fully customized for a variety of application requirements.
**Image Acquisition**

**N-SIM S**

**Image acquisition setting**
The N-SIM S can easily switch between 2D-SIM, 3D-SIM and TIRF-SIM modes. The JOBS flexible imaging sequence option enables seamless image acquisition between the N-SIM S, N-STORM and confocal microscopes.

**N-STORM**

**Image acquisition setting**
The N-STORM can easily switch between 2D-STORM and 3D-STORM image acquisition modes.

**Real-time display of localizations per frame**
During N-STORM image acquisition, the number of localized fluorescent molecules is displayed in real time using images and graphs. Clicking the Auto LP (Auto Laser Power) button automatically adjusts laser power, depending on the number of localized fluorescent spots.

**Display & Processing**

**N-SIM S**

**Image reconstruction**
Auto settings allow the software to automatically select the most appropriate reconstruction parameters for acquired images in order to reconstruct N-SIM S images. Users can further optimize reconstruction by manually adjusting these parameters. The reconstruction view allows users to preview the results of the selected reconstructed parameters on the current/selected frame, enabling efficient reconstruction parameter determination.

**N-STORM**

**Batch processing analysis**
Multiple N-STORM images can be simultaneously analyzed.

**3D display**
A major feature of the N-STORM is 3D super-resolution image acquisition and analysis. Acquired images can be displayed at any angle after analysis.
Explore the nano world with N-SIM S / N-STORM

Seamless switching between imaging modalities for multi-scale experiments

Combining the N-SIM S and N-STORM with a single Ti2-E inverted microscope expands the functionality of each individual technology. The N-SIM S enables acquisition of thicker volume images, thereby providing a more comprehensive molecular landscape for interpreting the single-molecule level data acquired by the N-STORM. The N-SIM S and/or N-STORM can be further combined with a confocal microscope such as the A1+. A desired location in a sample can be specified in a low-magnification/large FOV confocal image and acquired in super-resolution by simply switching the imaging method. Combining a confocal microscope with a super-resolution system can provide a method for gaining larger contextual views of the super-resolution information.

Simultaneous equipment of the A1+ Confocal Microscope and the N-SIM Super Resolution Microscope with a single imaging system enables multi-mode analysis. This multi-mode combination is advantageous in the study that requires wide and detailed views in a consistent manner. To analyze giant cells such as cultured mature osteoclasts with diameters of a few hundred microns, the user can acquire an image with a wide view using the A1+, select the area to be observed from that wide image, then switch to the N-SIM for ultrafine observation. Electron microscopy had been commonly used to observe podosomes that assemble to form ring-like structures called actin rings that are functionally associated with cellular adhesion and locomotion of osteoclasts. The N-SIM optically resolves individual podosomes, and enables the quantitative evaluation of osteoclast functions by analysis of the temporal and spatial dynamics of podosomes.

Dr. Tadahiro Iimura
Division of Bio-Imaging, Proteo-Science Center (PROS), Division of Analytical Bio-Medicine, Advanced Research Support Center (ADRES), Ehime University

“We found that CCR5, the target molecule for treatment of HIV infections, exists in osteoclasts, and that the functional loss of CCR5 impairs the bone-resorption activity of osteoclasts, resulting in a lower incidence of osteoporosis.” This finding suggests that CCR5-antagonist treatment may prevent bone-destructive diseases such as osteoporosis as well as HIV transmission.”

STORM imaging is the most important tool for our research as it is the only technique that allows us to measure the precise position and distribution of important signaling molecules within the chemical synapse on the nanoscale. But this data alone is like looking at stars in a dark sky. We need to use confocal microscopy to show in which context these molecular changes are taking place. After the physiological experiments we use confocal imaging for the morphological characterization of the cell type and the synapse. Then, we switch to STORM mode to gather information on the signaling molecules responsible for the physiological signaling. In this way we can correlate the molecular data, the anatomical data and the physiological data from the very same synapse. And this is very exciting!
