Volunteers needed for Research Study

Have you tried **ECT**, **psychotherapy**, and **medication** and are **still** suffering from **Depression**?

Deep Brain Stimulation (DBS), an experimental treatment, is now being used successfully in trials in Germany to treat Treatment Resistant Depression (TRD). In DBS for TRD a neurosurgeon implants a small electrode in the brain that delivers electrical stimulation to an area of the brain. The purpose of the study is to obtain a preliminary indication of the feasibility, safety and efficacy of DBS in the new site, supero-lateral branch of the medial forebrain bundle (slMFB).

You may qualify if you are:

- Between **22-65** years old
- And **currently** suffering from **Treatment Resistant Depression**
- The risks and benefits of taking part in this 2 year study will be **discussed with you**

Eligible study participants may receive study-related care which includes surgery, experimental device, and evaluation at no cost.
